

The Break Statement

The break keyword immediately terminates a loop, regardless of the condition. It is used to "jump out" of a repetitive cycle early.

```
for (int i = 0; i < 10; i++) {  
    if (i == 4) {  
        break; // Loop stops here  
    }  
    System.out.println(i);  
}
```

The Continue Statement

The continue keyword skips one iteration. It stops the current round and immediately jumps to the next cycle of the loop.

```
for (int i = 0; i < 10; i++) {  
    if (i == 4) {  
        continue; // Skips the rest of code for i=4  
    }  
    System.out.println(i);  
}
```

Key Differences

Command	Action
break	Stops the loop completely and moves to code after loop.
continue	Skips only current step and starts the next iteration.

Real-Life Use Cases

Search Logic: Stop searching once a target is found (use break).

```
if (userFound) break;
```

Data Validation: Skip negative or invalid processed entries (use continue).

```
if (price < 0) continue;
```

Control Summary

- Use **Break** when you are finished with the entire loop.
- Use **Continue** when you want to bypass specific data but keep looping.
- Both work in for, while, and do-while.
- In while loops, ensure counter updates occur before continue!
