

What are Class Methods?

Methods are functions declared inside a class that define the **behaviors** or actions of an object. They perform operations using the object's attributes.

```
public class Car {  
    public void fullThrottle() {  
        System.out.println("The car is going at maximum speed!");  
    }  
}
```

Static vs. Public Methods

A static method can be called without creating an object. A public (non-static) method **requires** an object instance to be called.

```
public static void main(String[] args) {  
    Car myCar = new Car(); // Create Object  
    myCar.fullThrottle();   // Call Public Method via Object  
}
```

Methods with Parameters

Methods can accept data to influence their actions. Use dot notation to pass arguments into these methods.

```
public void speed(int max) {  
    System.out.println("Max speed is: " + max);  
}  
  
// Execution:  
myCar.speed(200);
```

Behavior Checklist

- Methods must always be defined within the { } of a class.
- Use the **Dot Operator** (.) to trigger an object's behavior.
- Methods represent **Actions** (verbs), while attributes represent **Data** (nouns).
