

File Metadata

Accessing Properties with `getName()`

Reading File Properties

In Java, the `File` class doesn't just represent the content of a file, but also its metadata (information about the file itself). One of the most basic metadata tasks is retrieving the filename.

```
import java.io.File;

public class Main {
    public static void main(String[] args) {
        File myFile = new File("filename.txt");
        System.out.println("File name: " + myFile.getName());
    }
}
```

The `getName()` Method

This method returns a `String` representing the name of the file or directory denoted by this abstract pathname.

- **Input:** None.
- **Output:** The last name in the pathname's name sequence.
- **Note:** It does **not** check if the file actually exists on the disk; it simply parses the string used to create the `File` object.

Comparison: Name vs. Path

It is important to distinguish between the name of a file and its location on the system.

Method	Return Example
<code>getName()</code>	"filename.txt"
<code>getPath()</code>	"C:/users/docs/filename.txt" (or relative path)
<code>getAbsolutePath()</code>	The full root path to the file.
